# Lecture 03. Data Loading and Cleaning

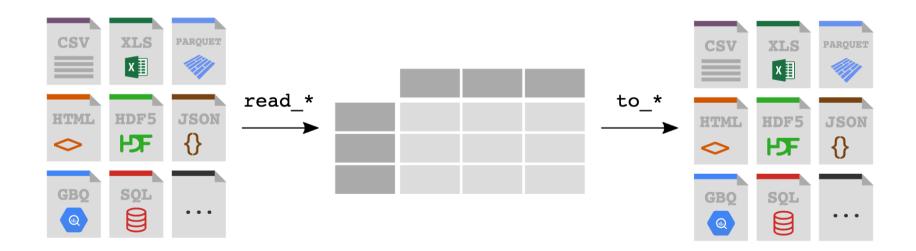

Instructor: Luping Yu

Mar 12, 2024

Accessing data is a necessary first step for using most of the tools in this course. We are going to be focused on data input and output using pandas.

## Reading and writing data in text format

pandas features a number of functions for reading tabular data as a DataFrame object.

The following table summarizes some of them, though read\_csv is likely the ones you'll use the most.

#### **Function Description**

| read\_csv | Load delimited data from a file, URL, or file-like object; use comma as default delimiter | read\_excel | Read tabular data from an Excel XLS or XLSX file | read\_stata | Read a dataset from Stata file format | read\_sas | Read a SAS dataset stored in one of the SAS system's custom storage formats | read\_html | Read all tables found in the given HTML document | read\_json | Read data from a JSON (JavaScript Object Notation) string representation | read\_pickle | Read an arbitrary object stored in Python pickle format | read\_sql | Read the results of a SQL query (using SQLAlchemy) as a pandas DataFrame

## Reading and Writing .csv (comma-separated values)

.csv is a delimited text file that uses a **comma** to separate values. A .csv file typically stores **tabular data** (numbers and text) in **plain text**.

Let's start with a small .csv text file: ex1.csv

```
In [1]: import pandas as pd
pd.read_csv('examples/ex1.csv') # relative path
```

 Out[1]:
 a
 b
 c
 d
 message

 0
 1
 2
 3
 4
 hello

 1
 5
 6
 7
 8
 world

 2
 9
 10
 11
 12
 foo

```
In [2]: # absolute path (absolute path differs between Windows and Mac)
pd.read_csv('/Users/luping/desktop/teaching/2024_fdap/examples/ex1.csv')
```

```
Out[2]:
            a b c d message
                              hello
                2 3 4
                             world
         1 5 6 7 8
         2 9 10 11 12
                               foo
         pandas read_csv() perform type inference. That means you don't necessarily have to specify which columns are numeric, integer,
        boolean, or string:
In [3]: df = pd.read_csv('examples/ex1.csv')
        df.dtypes
Out[3]: a
                      int64
                      int64
                      int64
                      int64
                     object
         message
         dtype: object
        A file will not always have a header row. Consider this file: <u>ex2.csv</u>
In [4]: pd.read_csv('examples/ex2.csv')
Out[4]:
               2 3 4 hello
                  7 8 world
         1 9 10 11 12
        To read this file, you have a couple of options. You can allow pandas to assign default column names, or you can specify names yourself:
```

In [5]: pd.read\_csv('examples/ex2.csv', names=['a', 'b', 'c', 'd', 'message'])

```
Out[5]: a b c d message

0 1 2 3 4 hello

1 5 6 7 8 world

2 9 10 11 12 foo
```

Suppose you wanted the message column to be the index of the returned <code>DataFrame</code> . You can use the <code>index\_col</code> argument:

Handling missing values is an important and frequently nuanced part of the file parsing process. Consider this file: ex3.csv

Missing data is usually either not present (empty string) or marked by some sentinel value, such as NA and NULL.

```
In [8]: df = pd.read_csv('examples/ex3.csv')
```

pd.notnull(df) Out[8]: something d message 0 True True True True True False 1 True True False True 2 True True True True True True Using to\_csv() method, we can write the data out to a comma-separated file: df.to\_csv('examples/out1.csv') With no other options specified, both the row and column labels are written. Both of these can be disabled:

## Parameters of data loading functions

Because of how messy data in the real world can be, data loading functions (especially read\_csv()) have grown very complex in their options over time. The **online pandas documentation** has many examples about how each of them works.

API reference (pandas documentation) of read\_csv(): https://pandas.pydata.org/docs/reference/api/pandas.read\_csv.html

### Reading Microsoft excel files

In [10]: df.to\_csv('examples/out2.csv', index=False)

pandas also supports reading tabular data stored in Excel 2003 (and higher) files using pandas.read\_excel() function:

Internally these tools use the add-on packages **xIrd** and **openpyxI** to read XLS and XLSX files, respectively. You may need to install these manually with pip.

```
In [ ]: df = pd.read_excel('examples/ex1.xlsx', 'Sheet1')
```

df

To write pandas data to Excel format, you can pass a file path to to\_excel():

```
In [ ]: df.to_excel('examples/out1.xlsx')
```

## Data cleaning and preparation

During the course of doing data analysis and modeling, a significant amount of time is spent on data preparation: **loading**, **cleaning**, **transforming**, and **rearranging**. Such tasks are often reported to take up 80% or more of an analyst's time.

Sometimes the way that data is stored in files or databases is not in the right format for a particular task. Fortunately, pandas provides you with a high-level, flexible, and fast set of tools to enable you to manipulate data into the right form.

#### **Handling Missing Data**

Missing data (**NA**, which stands for **not available**) occurs commonly in many data analysis applications. For numeric data, pandas uses the floating-point value **NaN** (not a number) to represent missing data.

With DataFrame objects, you may want to drop rows or columns that are all NA or only those containing any NAs.

dropna() by default drops any row containing a missing value:

```
Out[13]: 0 1 2
        0 1.0 6.5 3.0
        1 1.0 NaN NaN
        2 NaN NaN NaN
        3 NaN 6.5 3.0
In [14]: df.dropna()
Out[14]: 0 1 2
        0 1.0 6.5 3.0
        Passing how='all' will only drop rows that are all NA:
In [15]: df.dropna(how='all')
Out[15]: 0 1 2
        0 1.0 6.5 3.0
        1 1.0 NaN NaN
        3 NaN 6.5 3.0
        To drop columns in the same way, pass axis=1:
In [16]: df[3] = None
        df
```

```
Out[16]:

0 1 2 3

0 1.0 6.5 3.0 None

1 1.0 NaN NaN NaN None

2 NaN NaN NaN None

3 NaN 6.5 3.0 None

Out[17]:

0 1 2

0 1.0 6.5 3.0

1 1.0 NaN NaN

2 NaN NaN NaN

3 NaN 6.5 3.0
```

## Filling In Missing Data

Rather than filtering out missing data, you may want to fill in the "holes" in any number of ways. The fillna method is the function to use.

Calling fillna with a constant replaces missing values with that value:

Out[18]:		class participation	homework	midterm	final
	0	10.0	30.0	20.0	40.0
	1	8.0	25.0	15.0	35.0
	2	6.0	20.0	10.0	NaN
	3	NaN	NaN	NaN	NaN
	4	NaN	NaN	10.0	30.0

In [19]: df.fillna(5)

Out [19]: class participation homework midterm final

•	•			
0	10.0	30.0	20.0	40.0
1	8.0	25.0	15.0	35.0
2	6.0	20.0	10.0	5.0
3	5.0	5.0	5.0	5.0
4	5.0	5.0	10.0	30.0

Calling fillna() with a dict, you can use a different fill value for each column:

In [20]: df.fillna({'class participation': 5, 'final': 30})

Out [20]: class participation homework midterm final

	ciass participation	on nome	WOLK IIIIG	term	IIIIai
	<b>0</b> 10	0.0	30.0	20.0	40.0
	1 8	3.0	25.0	15.0	35.0
	<b>2</b> 6	5.0	20.0	10.0	30.0
;	<b>3</b> 5	5.0	NaN	NaN	30.0
	4 5	5.0	NaN	10.0	30.0

#### The interpolation methods can be used with fillna:

In [21]: df.fillna(method='ffill')

Out[21]:

	class participation	homework	midterm	final
C	10.0	30.0	20.0	40.0
•	8.0	25.0	15.0	35.0
2	6.0	20.0	10.0	35.0
3	6.0	20.0	10.0	35.0
4	6.0	20.0	10.0	30.0

With fillna you can do lots of other things with a little creativity. For example, you might pass the mean or median value of a Series:

In [22]: df.describe() #summary statistics

Out[22]:

count       3.0       3.0       4.000000       3.0         mean       8.0       25.0       13.750000       35.0         std       2.0       5.0       4.787136       5.0         min       6.0       20.0       10.000000       30.0         25%       7.0       22.5       10.000000       32.5         50%       8.0       25.0       12.500000       35.0         75%       9.0       27.5       16.250000       37.5         max       10.0       30.0       20.000000       40.0		class participation	homework	midterm	final
std       2.0       5.0       4.787136       5.0         min       6.0       20.0       10.000000       30.0         25%       7.0       22.5       10.000000       32.5         50%       8.0       25.0       12.500000       35.0         75%       9.0       27.5       16.250000       37.5	count	3.0	3.0	4.000000	3.0
min       6.0       20.0       10.000000       30.0         25%       7.0       22.5       10.000000       32.5         50%       8.0       25.0       12.500000       35.0         75%       9.0       27.5       16.250000       37.5	mean	8.0	25.0	13.750000	35.0
25%       7.0       22.5       10.000000       32.5         50%       8.0       25.0       12.500000       35.0         75%       9.0       27.5       16.250000       37.5	std	2.0	5.0	4.787136	5.0
50%       8.0       25.0       12.500000       35.0         75%       9.0       27.5       16.250000       37.5	min	6.0	20.0	10.000000	30.0
<b>75%</b> 9.0 27.5 16.250000 37.5	25%	7.0	22.5	10.000000	32.5
7677 010 2710 101200000 0710	50%	8.0	25.0	12.500000	35.0
max 10.0 30.0 20.000000 40.0	75%	9.0	27.5	16.250000	37.5
	max	10.0	30.0	20.000000	40.0

In [23]: df.fillna(df.mean())

Out[23]:		class participation	homework	midterm	final
	0	10.0	30.0	20.00	40.0
	1	8.0	25.0	15.00	35.0
	2	6.0	20.0	10.00	35.0
	3	8.0	25.0	13.75	35.0
	4	8.0	25.0	10.00	30.0

# **Removing Duplicates**

Duplicate rows may be found in a DataFrame for any number of reasons. Here is an example:

```
      0
      one
      1

      1
      two
      1

      2
      one
      2

      3
      two
      3

      4
      one
      3

      5
      two
      4

      6
      two
      4
```

The DataFrame method duplicated() returns a boolean Series indicating whether each row is a duplicate (has been observed in a previous row) or not:

```
In [25]: df.duplicated()
Out[25]: 0
               False
               False
               False
               False
               False
               False
                True
          dtype: bool
          Relatedly, drop_duplicates() returns a DataFrame where the duplicated array is False:
In [26]: df.drop_duplicates()
Out[26]:
              k1 k2
          0 one 1
          1 two
          2 one
                  2
          3 two
          4 one 3
          5 two 4
          drop_duplicates() considers all of the columns; alternatively, you can specify any subset of them to detect duplicates.
          Suppose we had an additional column of values and wanted to filter duplicates only based on the 'k1' column:
In [27]: df['k3'] = range(7)
```

df

```
Out[27]:
            k1 k2 k3
         0 one 1 0
         1 two 1 1
         2 one
         3 two
         4 one
         5 two
         6 two 4 6
In [28]: df.drop_duplicates(['k1'])
Out[28]:
            k1 k2 k3
         0 one
         1 two 1 1
         duplicated() and drop_duplicates() by default keep the first observed value combination. Passing keep='last' will return
        the last one:
In [29]: df.drop_duplicates(['k1', 'k2'], keep='last')
```

```
Out[29]: k1 k2 k3

O one 1 O

1 two 1 1

2 one 2 2

3 two 3 3

4 one 3 4

6 two 4 6
```

### Vectorized string functions in pandas

Cleaning up a messy dataset for analysis often requires a lot of string **regularization**. For example, a column containing strings will sometimes have missing data:

```
In [30]: df = pd.Series({'Dave': 'dave@google.com',
                          'Jack': 'jack@xmu.edu.cn',
                          'Steve': 'steve@gmail.com',
                          'Rose': 'rose@xmu.edu.cn',
                          'Tony': None})
         df
                   dave@google.com
Out[30]: Dave
                   jack@xmu.edu.cn
          Jack
                   steve@gmail.com
          Steve
          Rose
                   rose@xmu.edu.cn
          Tony
                              None
          dtype: object
```

Series has array-oriented methods for string operations that skip NA values. These are accessed through Series's str attribute.

For example, we could check whether each email address has 'xmu.edu' in it with str.contains:

```
In [31]: df.str.contains('xmu.edu')
Out[31]: Dave
                   False
                    True
          Jack
          Steve
                   False
          Rose
                    True
          Tony
                    None
          dtype: object
         You can similarly slice strings using this syntax:
In [32]: df.str[:5]
Out[32]: Dave
                   dave@
          Jack
                   jack@
          Steve
                   steve
          Rose
                   rose@
          Tony
                    None
          dtype: object
In [33]: df.str.split('@')
Out[33]: Dave
                   [dave, google.com]
          Jack
                   [jack, xmu.edu.cn]
                   [steve, gmail.com]
          Steve
          Rose
                   [rose, xmu.edu.cn]
          Tony
                                  None
          dtype: object
In [34]: df.str.split('@').str.get(0)
Out[34]: Dave
                    dave
          Jack
                    jack
          Steve
                   steve
          Rose
                    rose
          Tony
                    None
          dtype: object
         Partial listing of vectorized string methods.
```

#### **Method Description**

|cat|Concatenate strings element-wise with optional delimiter |contains|Return boolean array if each string contains pattern/regex |count|Count occurrences of pattern |extract|Use a regular expression with groups to extract one or more strings from a Series of strings |endswith|Equivalent to x.endswith(pattern) for each element |startswith|Equivalent to x.startswith(pattern) for each element |findall|Compute list of all occurrences of pattern/regex for each string |get|Index into each element (retrieve i-th element) |join|Join strings in each element of the Series with passed separator |len|Compute length of each string |lower,upper|Convert cases;equivalent to x.lower() or x.upper() for each element |match|Use re.match with the passed regular expression on each element |replace|Replace occurrences of pattern/regex with some other string |slice|Slice each string in the Series |split|Split strings on delimiter or regular expression |strip|Trim whitespace from both sides, including newlines
